

# COMP7409C Machine Learning in Trading and Finance

This course offers an overview of Machine Learning to students and prepares them with essential skills to apply it in problem-solving for Trading and Finance.

# About this course

- Instructor
  - H.F. TING
- TAs:
  - Jolly CHENG
  - Karen CHOW

# About this course

## Assessment

- Three programming assignments (65%):
  - A1: 20%
  - A2: 20%
  - A3: 25%
- Final Exam (35%)

# Topics to be covered

- Basics of Data Science
- Basics of Machine Learning
- Financial fault detection using ML
- Financial forecasting using ML
- NLP and Sentiment Analysis
- Trading bot with reinforcement learning
- Recommendation system
- Option pricing with deep learning

# Assignment release schedule

L1 11/6

L2 14/6

L3 18/6

L4 25/6      release A1

L5 28/6

L6 2/7

L7 9/7      release A2

L8 12/7

L9 16/7

L10 23/7      release A3

# Programming Languages: Python

## Why Python?

- Free & open source
- Simple syntax, easy to self-learn and understand
- General-purpose programming language
- Has a rich set of libraries and packages designed for data science and machine learning
- Good memory management and high performance

# Programming Languages for this course: Python

## Why Python?

- Free & open source
- Simple syntax, easy to self-learn and understand
- General-purpose programming language
- Has a rich set of libraries and packages designed for data science and machine learning
- Good memory management and high performance

But,

- I don't know where to find these packages  
and even if I know where to download the package I need,
- I don't know how to install it; different packages would have different installation procedures.

# Anaconda Repository (Anaconda Repo)

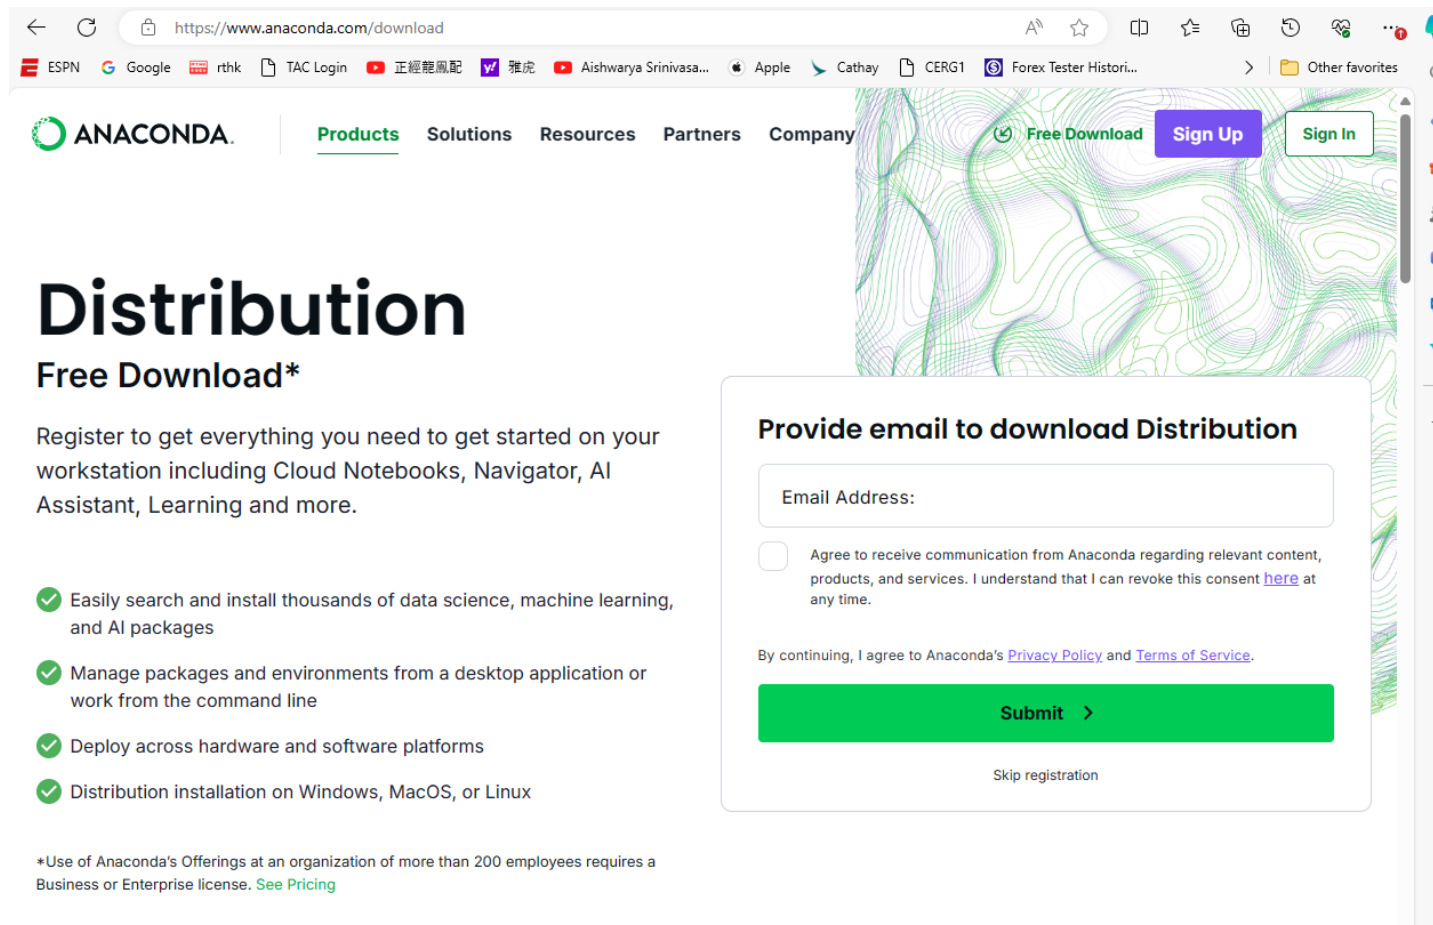

- Anaconda repo is an open-source distribution of Python programs for scientific computing, data science, and machine learning.
- It is a cloud-based platform where users can find and share packages and programs.
- It includes thousands of packages for data science, machine learning, and scientific computing.
- It makes it easy for users to find and install the packages they need for their data analysis and modelling tasks.

# How to install Anaconda?

Simply download and install **Anaconda Distribution** via

<https://www.anaconda.com/download>

The screenshot shows the Anaconda website's download page. The browser's address bar displays <https://www.anaconda.com/download>. The website's navigation bar includes the Anaconda logo, a 'Products' dropdown menu, and links for 'Solutions', 'Resources', 'Partners', and 'Company'. On the right side of the navigation bar, there are buttons for 'Free Download', 'Sign Up', and 'Sign In'. The main heading on the page is 'Distribution', followed by the sub-heading 'Free Download\*'. Below this, a paragraph states: 'Register to get everything you need to get started on your workstation including Cloud Notebooks, Navigator, AI Assistant, Learning and more.' A list of four benefits is provided, each preceded by a green checkmark: 'Easily search and install thousands of data science, machine learning, and AI packages', 'Manage packages and environments from a desktop application or work from the command line', 'Deploy across hardware and software platforms', and 'Distribution installation on Windows, MacOS, or Linux'. At the bottom left, a footnote reads: '\*Use of Anaconda's Offerings at an organization of more than 200 employees requires a Business or Enterprise license. See Pricing'. A registration modal is open in the center-right of the page, titled 'Provide email to download Distribution'. It contains an 'Email Address:' input field, a checkbox for agreeing to communication, and a green 'Submit >' button. A link for 'Skip registration' is located at the bottom of the modal.

ANACONDA. Products Solutions Resources Partners Company

## Distribution

### Free Download\*

Register to get everything you need to get started on your workstation including Cloud Notebooks, Navigator, AI Assistant, Learning and more.

- ✓ Easily search and install thousands of data science, machine learning, and AI packages
- ✓ Manage packages and environments from a desktop application or work from the command line
- ✓ Deploy across hardware and software platforms
- ✓ Distribution installation on Windows, MacOS, or Linux

\*Use of Anaconda's Offerings at an organization of more than 200 employees requires a Business or Enterprise license. See Pricing

#### Provide email to download Distribution

Email Address:

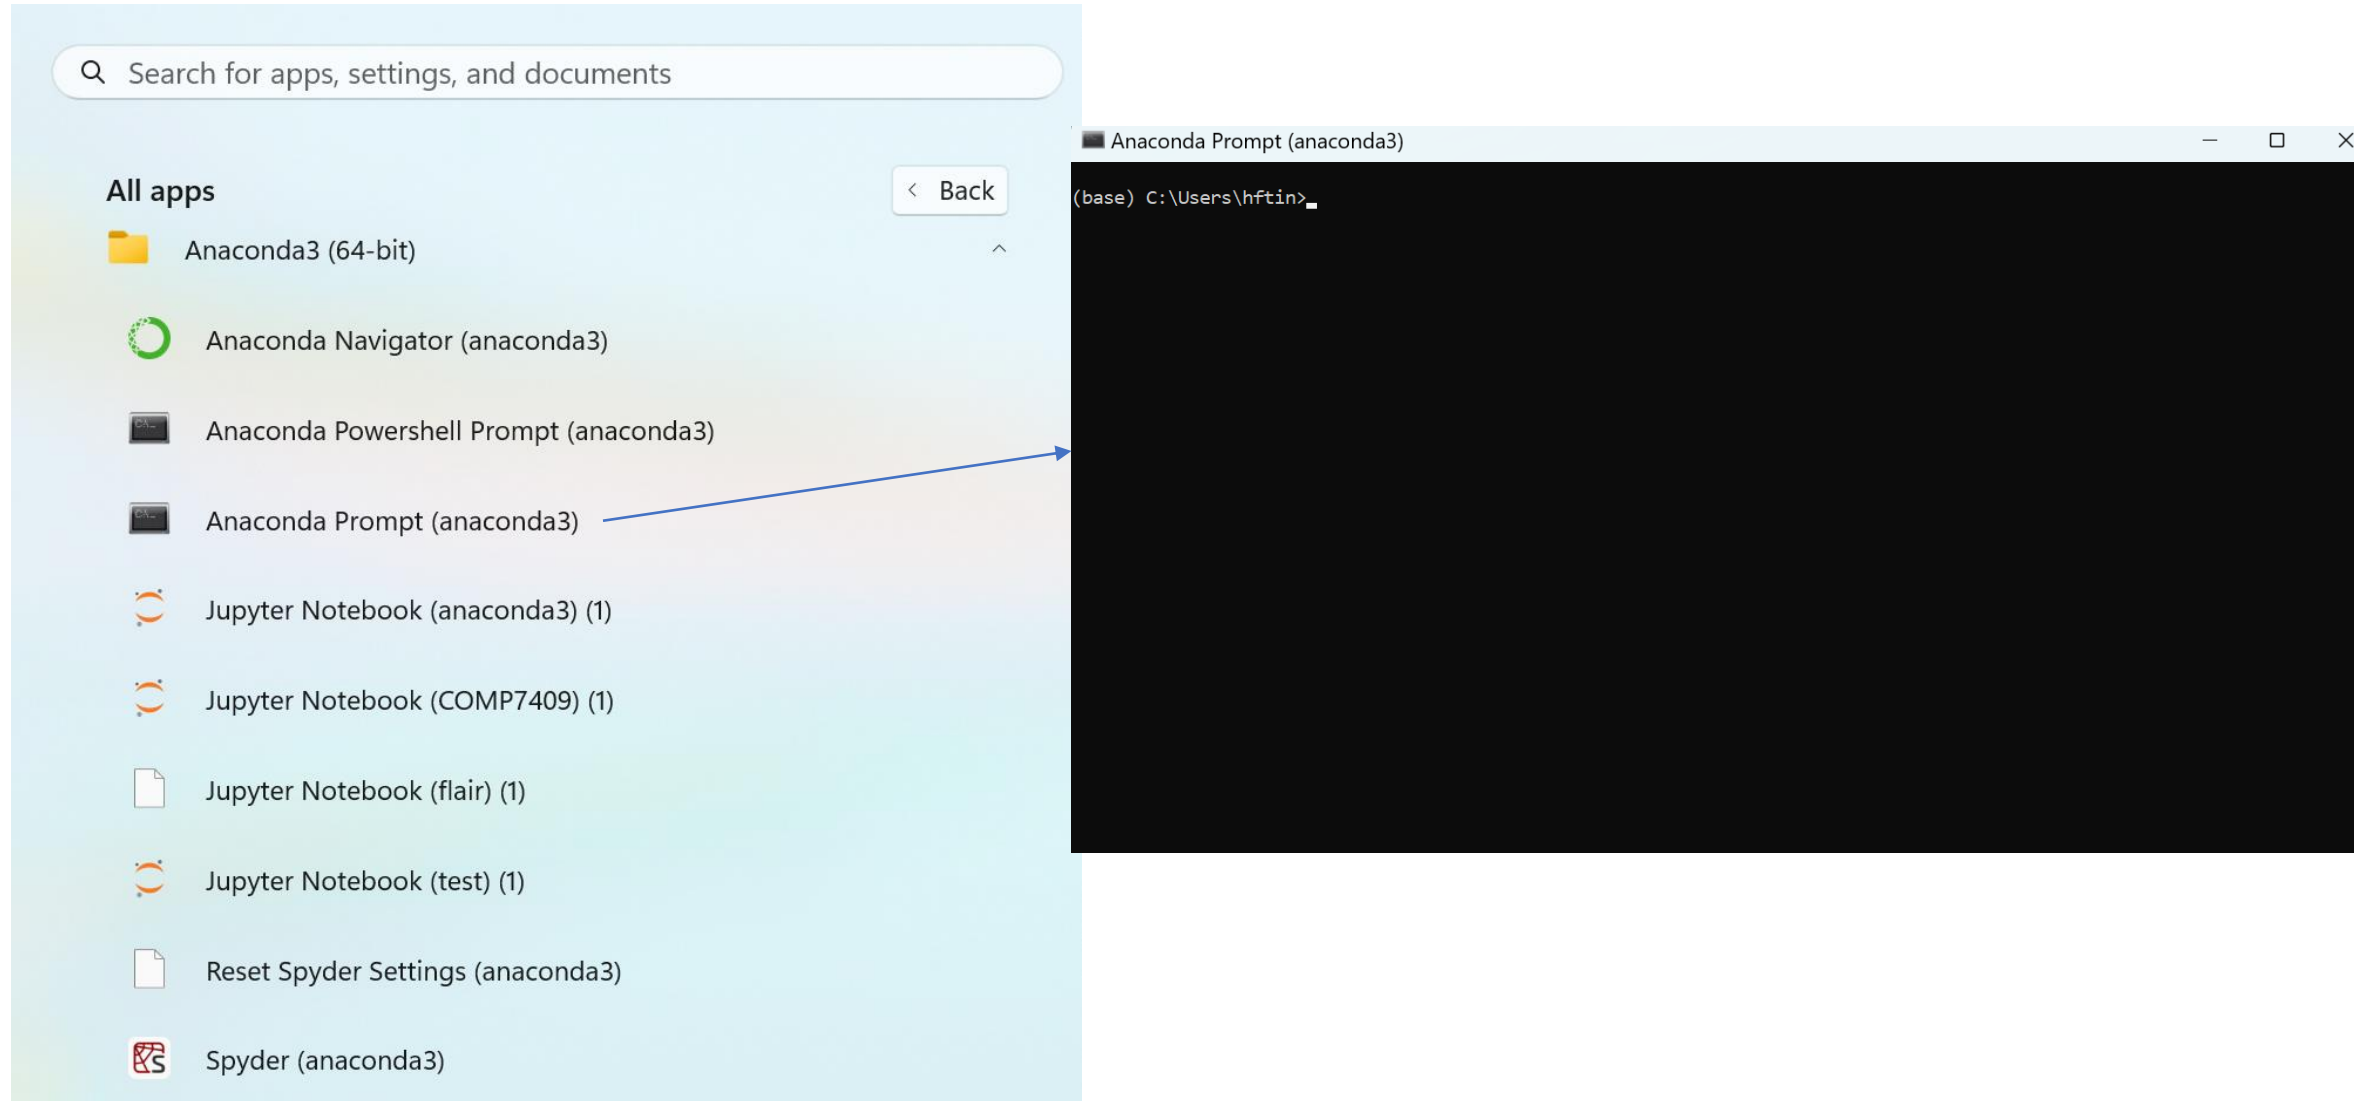

☐ Agree to receive communication from Anaconda regarding relevant content, products, and services. I understand that I can revoke this consent [here](#) at any time.

By continuing, I agree to Anaconda's [Privacy Policy](#) and [Terms of Service](#).

# There are many other useful tools from Anaconda

# There are many other useful tools from Anaconda

# The Python Package Index (PyPI)

- In some of our examples we will use the **pip** command to install directly package from **PyPI** in our program. (You will know why in a minute)
- The Python Package Index is a repository of software packages maintain by the Python Software Foundation.
- pip is the package managers for PyPI (more info later).

# IPython and Jupyter Notebook

- IPython, also known as Interactive Python, is a powerful tool that allows you to write Python program interactively; i.e., you can type a fragment of the program, then run it to see the results, make the necessary changes, and once satisfied, continue to input the following statements.

We will use **iPython** and **Jupyter Notebook** to write our Python programs.

# IPython and Jupyter Notebook

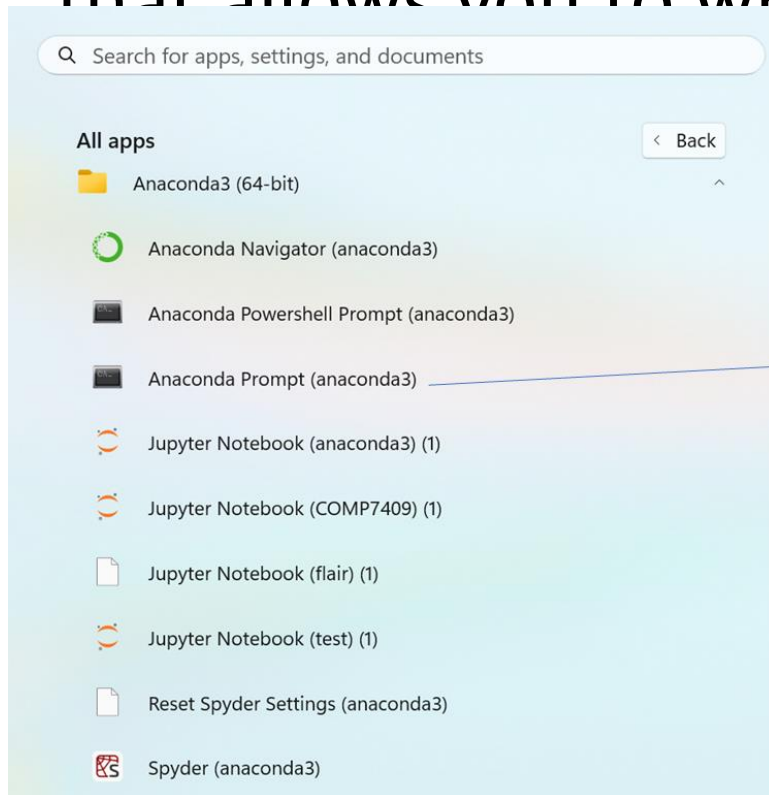

- **IPython**, also known as Interactive Python, is a powerful tool that allows you to write Python program interactively; i.e., you can type a fragment of the program, then run it to see the results, make necessary changes, and once satisfied, continue to input more statements.

# IPython and Jupyter Notebook

- **IPython**, also known as Interactive Python, is a powerful tool that allows you to write Python program interactively; i.e., enter the program then run it to see the results. You need to follow the following steps to install it:

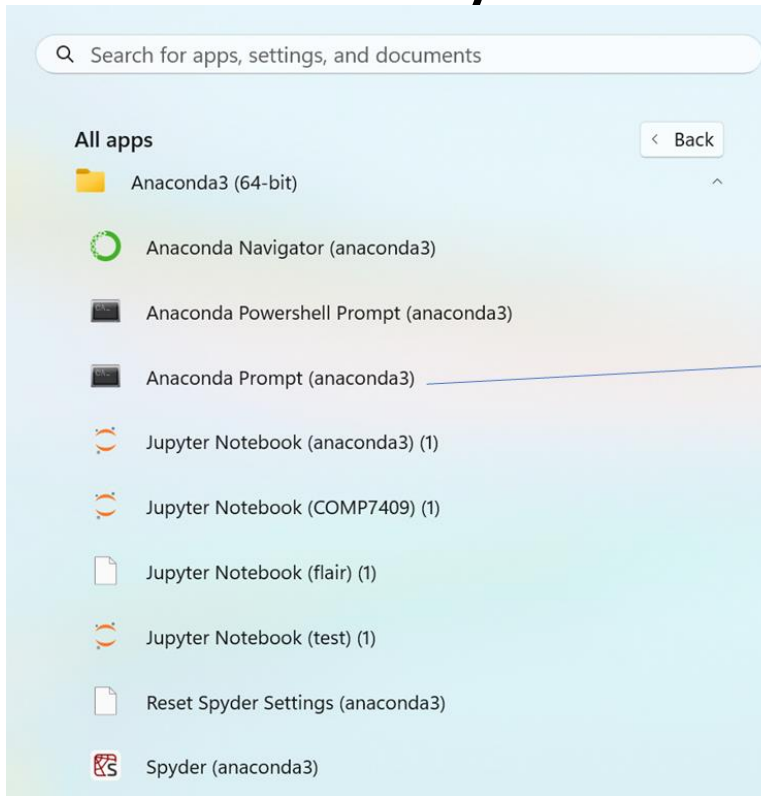

```
Anaconda Prompt (anaconda3)
(base) C:\Users\hftin>conda list
# packages in environment at C:\Users\hftin\anaconda3:
# Name                    Version           Build    Channel

# IPython and Jupyter Notebook

**Jupyter Notebook** is a browser-based tool that is the IDE (Integrated Development Environment) for IPython. Beside the standard output, it also support graphs, audio and video output. It contains an ordered list of input/output cells. You write a fragment of your program in an input cell, run it and the result will be displayed in the output cell.

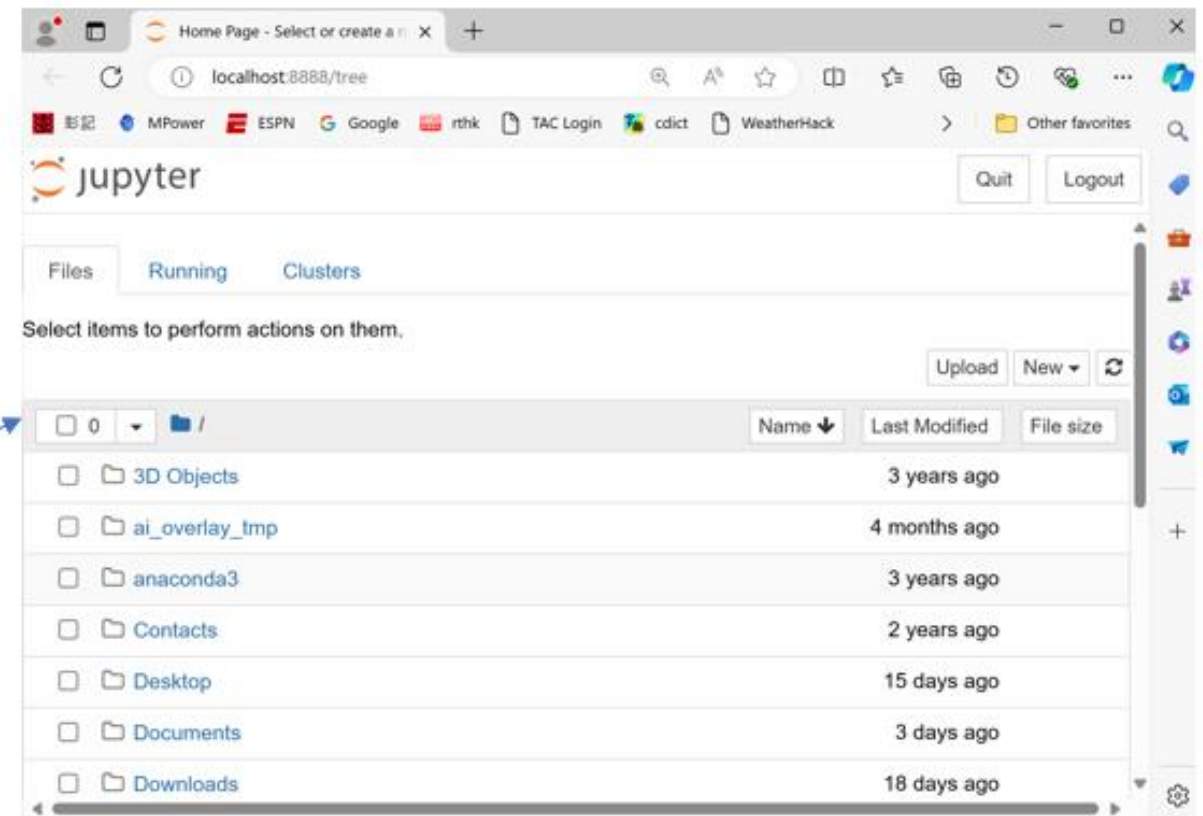

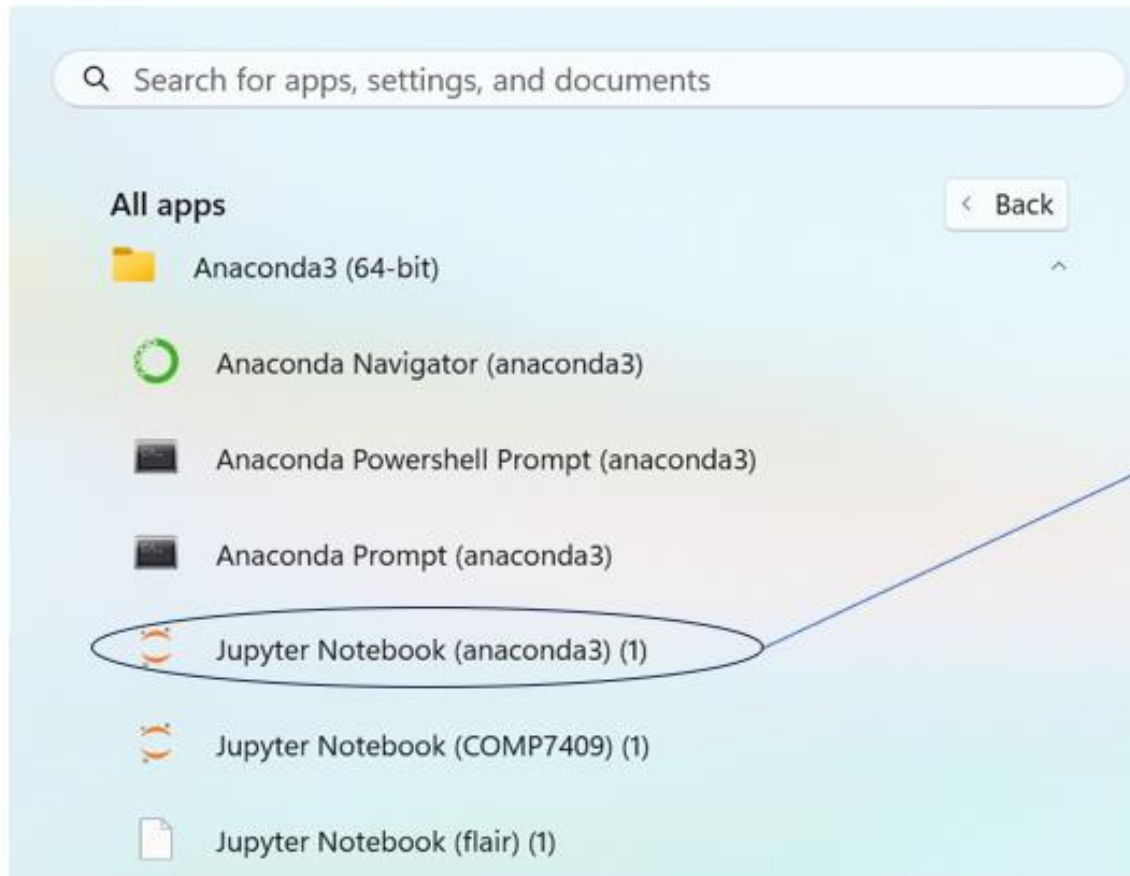

# Another way for opening Jupyter Notebook

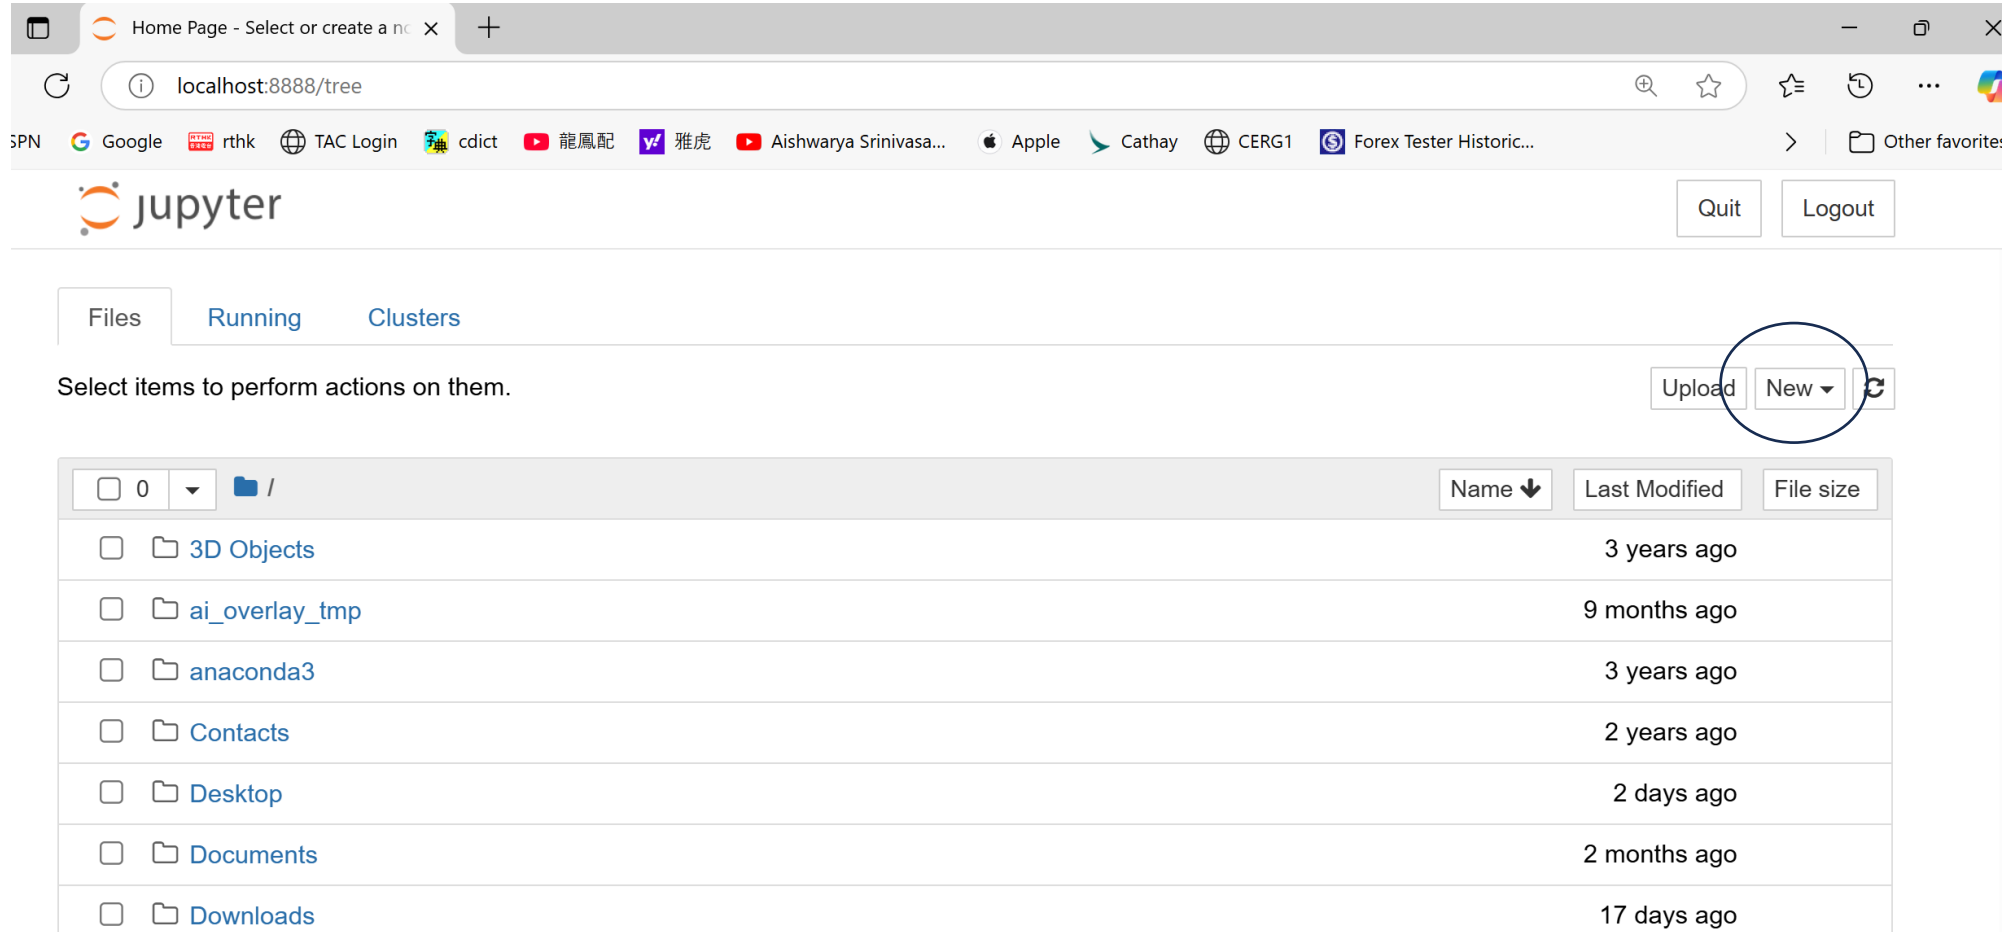

# IPython and Jupyter Notebook

Another way to invoke Jupyter NB

# The browser-based interface of Jupyter NB

The screenshot displays the Jupyter Notebook web interface in a browser. The address bar shows `localhost:8888/tree`. The Jupyter logo is in the top left, and "Quit" and "Logout" buttons are in the top right. Below the logo are tabs for "Files", "Running", and "Clusters", with "Files" being the active tab. A message "Select items to perform actions on them." is followed by "Upload", "New" (with a dropdown arrow), and a refresh icon. The "New" button is circled in blue. Below this is a file browser table with columns for selection, name, last modified, and file size.

	Name ↓	Last Modified	File size
<input type="checkbox"/> 0	/		
<input type="checkbox"/>	3D Objects	3 years ago	
<input type="checkbox"/>	ai_overlay_tmp	9 months ago	
<input type="checkbox"/>	anaconda3	3 years ago	
<input type="checkbox"/>	Contacts	2 years ago	
<input type="checkbox"/>	Desktop	2 days ago	
<input type="checkbox"/>	Documents	2 months ago	
<input type="checkbox"/>	Downloads	17 days ago	

# An example: JupyterOutput.ipynb

```
import matplotlib.pyplot as plt
import numpy as np

x = np.linspace(0, 10, 100)
y = np.cos(x)

plt.plot(x, y)
plt.show()
```

Note: A Jupyter notebook has extension .ipynb, not .py. You cannot run Jupyter notebook on a Python IDE, say IDLE. But Jupyter allows you to convert a .ipynb file to a .py file.

# An example: JupyterOutput.ipynb

```
import matplotlib.pyplot as plt
import numpy as np

x = np.linspace(0, 10, 100)
y = np.cos(x)

plt.plot(x, y)
plt.show()
```

# Colab: Running Jupyter NB on internet

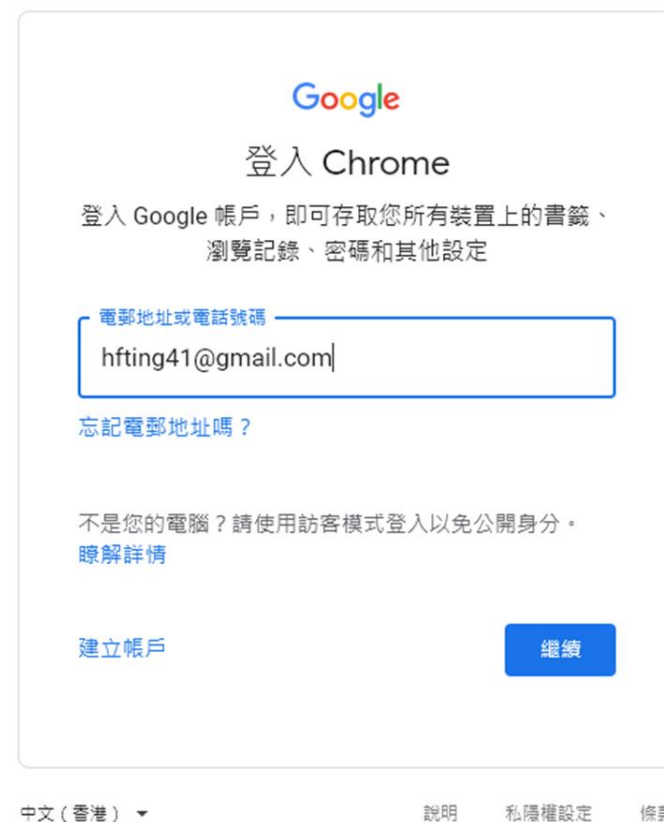

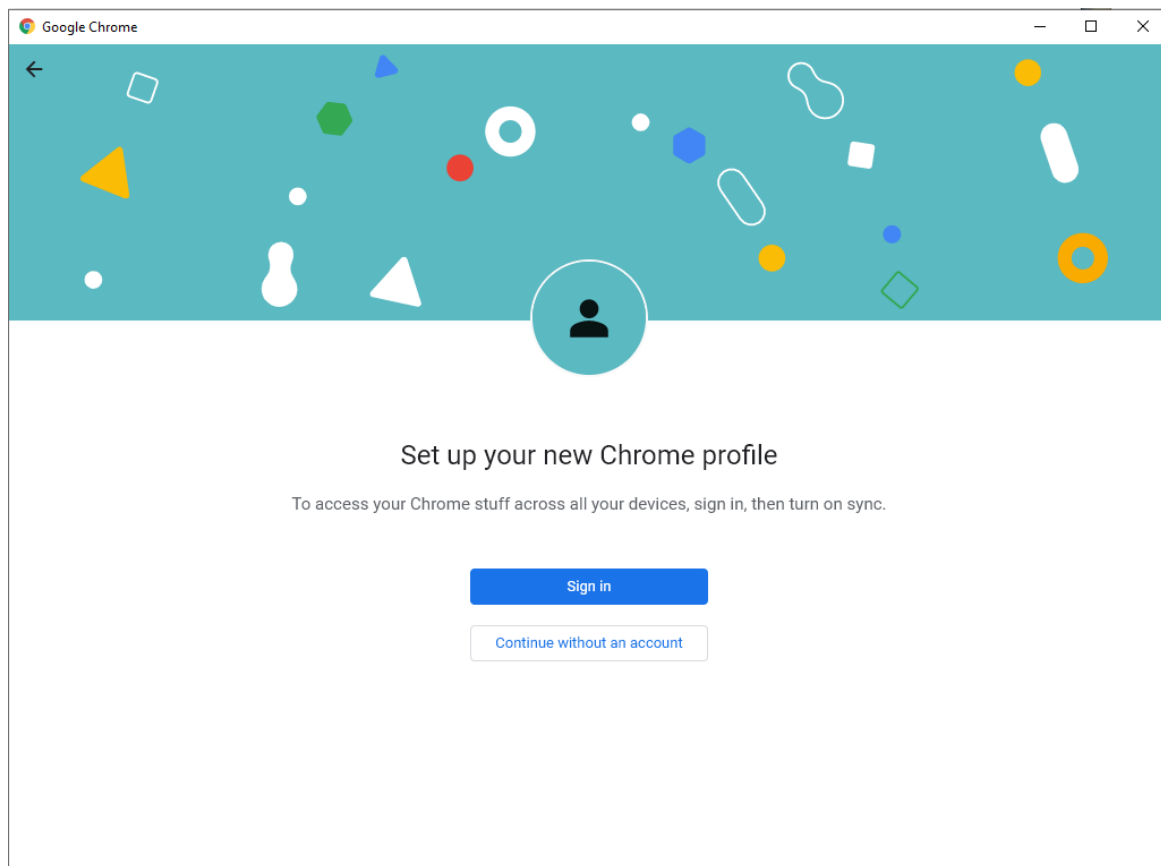

- Jupyter notebook is a browser-based tool
- You open and execute it using any web browser.
- What we have done:
  - We write our NB in our local computer: you open a web browser (e.g., Microsoft Edge) locally to run the notebook.
- But, we can also write and execute our NB on some remote servers on internet.

# Colab: Running Jupyter NB on internet

- In the last few years, Google's Colaboratory (Colab) becomes one of the most popular cloud platform for data scientists to develop data science applications and perform data analytics.
- Colab supports a convenient environment that allows us to store our Jupyter notebooks on [Google Drive](#) and execute them using Google's cloud server.
- You don't need to worry about the installation of most packages as you run your programs in its cloud, though for some special ones, you still need to install it using [pip](#), which is a package installer for installing packets in the repository Python Package Index (PyPI).

# How to use Colab?

## 1. Sign in your Google account

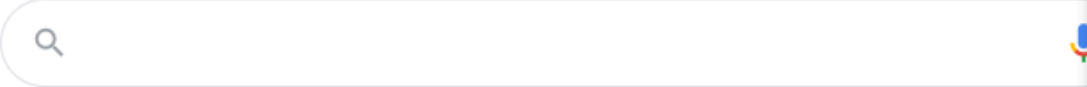

## 2. Open google drive

Apps Aishwarya Srinivasa... Apple Cathay cdict CERGI China 2021: The big... China 2021: The big... China 2021: The big... » Other bookmarks Reading list

### 3. Create a folder

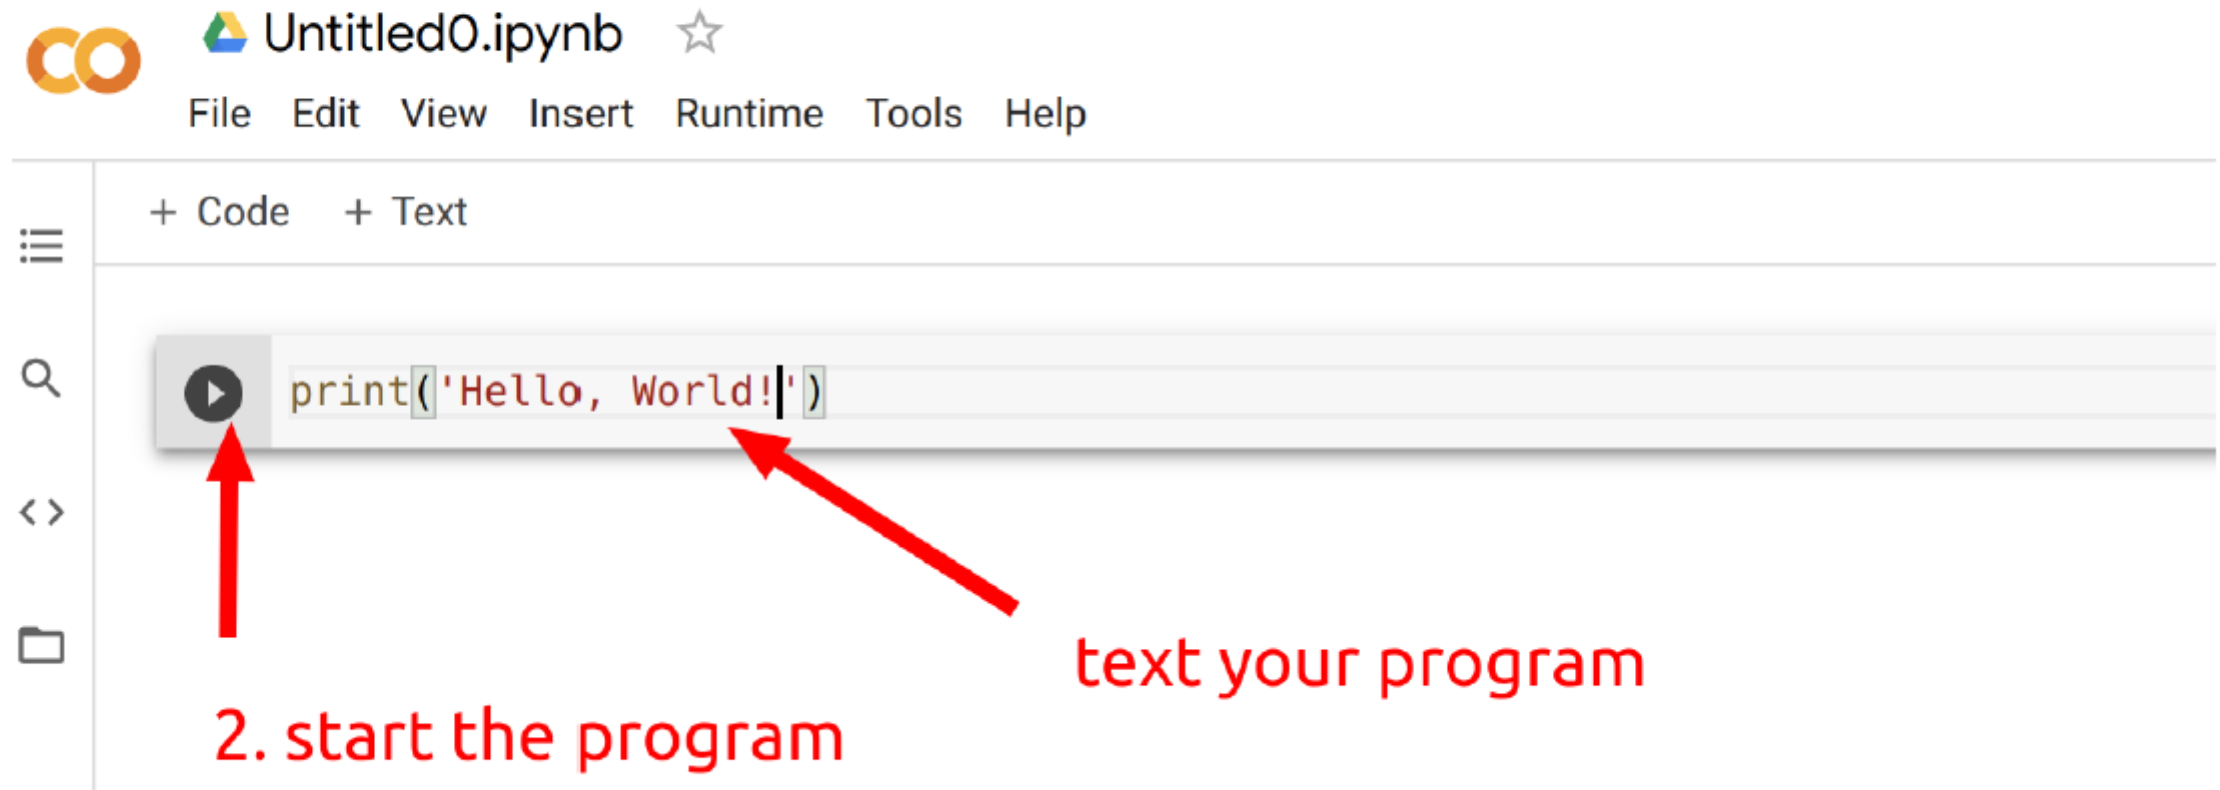

## 4. Move to that folder, and create a new “Colab” page

4. You can input your program now

## How to install package when using colab

Like Anaconda, colab has pre-installed many popular libraries and packages like numpy, panda and matplotlib. For other packages, you can use the command **pip** to install those packages from Python Package Index.

For example,

```
!pip install numpy
```

```
Requirement already satisfied: numpy in /usr/local/lib/python3
```

```
i = 0
while (i < 6):
    print("Hello")
    i = i + 1
```

```
Hello
Hello
Hello
```

# What's next?

- We will now cover some basic background:
  - Advanced Python
  - Numpy
  - Pandas
  - Machine Learning basics
- **Important:** You need to know how to program in Python. This course will not teach Python basics.

# Advanced Python: Classes and Objects

- Python is an object-oriented programming language.
- The machine language packages available in popular libraries such as Scikit-learn and Tensorflow are all implemented using classes and objects.

# Classes and Objects in Python

- Classes are the blueprint/recipe for object creation.
- Basically, classes are composed of two things:
  - Attributes: They are “variables” used to store data
  - Methods: They are functions defined within class.
- Objects are instances of classes.

## An example: a simple class (simple\_class.jpynb)

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

---

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

← Name of the class

← The `__init__` function is **compulsory**. It is called every time a new object of this class is created.

---

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

- The parameter **self** is very special. We use it to access the attributes and methods defined within the class . Note that it must be the first parameter in every method of the class.

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

The other parameter a is used to pass value to the object to be created.

---

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

This class has

- two attributes: self.a and self.b, and
- one method: f

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

The statement is to create an instance of the class simple, and assign a reference of this instance to the variable q.

But, exactly what will happen when this statement is executed?

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:  
(1) Create an object of **simple**

objx

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of `simple`
- (2) Execute `__init__`

objx

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of **simple**
- (2) Execute `__init__`:
  - (i) arguments passing:  
**self** <= **objx**; a <= "Try me!"

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of **simple**
- (2) Execute `__init__`:
  - (i) arguments passing:  
**self** <= **objx**; a <= "Try me!"
  - (ii) execute stmt in the body:

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of **simple**
- (2) Execute `__init__`:
  - (i) arguments passing:  
**self** <= **objx**; a <= "Try me!"
  - (ii) execute stmt in the body:  
self.a (== objx.a) ← a (== "Try me!")

self: objx  
a: "Try me!"

objx

objx.a = "Try me!"

# An example: a simple class

```

    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of **simple**
- (2) Execute `__init__`:
  - (i) arguments passing:  
**self**  $\leftarrow$  **objx**; a  $\leftarrow$  "Try me!"
  - (ii) execute stmt in the body:  
self.a ( $==$  objx.a)  $\leftarrow$  a ( $==$  "Try me!")  
self.b ( $==$  objx.b)  $\leftarrow$  13

self: objx  
a: "Try me!"

objx

objx.a = "Try me!"  
objx.b = 13

# An example: a simple class

```
class simple:
    def __init__(self, a):
        self.a = a
        self.b = 13

    def f(self):
        print("b = ", self.b)
```

```
q = simple("Try me!")
print(q.a)
q.f()
```

```
Try me!
b = 13
```

Following are what will happen:

- (1) Create an object of **simple**
- (2) Execute `__init__`:
  - (i) arguments passing:  
**self**  $\leftarrow$  **objx**; a  $\leftarrow$  "Try me!"
  - (ii) execute stmt in the body:  
self.a ( $==$  objx.a)  $\leftarrow$  a ( $==$  "Try me!")  
self.b ( $==$  objx.b)  $\leftarrow$  13
  - (iii) return self ( $==$  objx) and  
assign the returned value to q

# List comprehension

- A fast and elegant way to construct a list

## Example – No List Comprehension

```
# Square all values
li = [2, 5, 3, 7]
r = []
for i in li:
    r.append(i ** 2)
print(r)
```

## OUTPUT

```
[4, 25, 9, 49]
```

## Example 1 – List Comprehension

```
# Square all values
li = [2, 5, 3, 7]
r = [i ** 2 for i in li]
print(r)
```

## OUTPUT

```
[4, 25, 9, 49]
```

# List comprehension

- A fast and elegant way to construct a list

## Example - No List Comprehension

```
# Filter values above 3
li = [2, 5, 3, 7]
r = []
for i in li:
    if i > 3:
        r.append(i)
print(r)
```

OUTPUT

[5, 7]

## Example 2 - List Comprehension

```
# Filter values above 3
li = [2, 5, 3, 7]
r = [i for i in li if i > 3]
print(r)
```

OUTPUT

[5, 7]

# List comprehension

- A fast and elegant way to construct a list

```
coordinates = [(x, y) for x in range(3) for y in range(3)]  
  
print(coordinates)
```

## Output

```
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0), (2, 1),  
(2, 2)]
```

# List comprehension

- A fast and elegant way to construct a list

```
coordinates = [(x, y) for x in range(3) for y in range(3)]  
  
print(coordinates)
```

≈

```
coordinates = []  
for x in range(3):  
    for y in range(3):  
        coordinates.append((x,y))  
print(coordinates)
```

# Dictionary comprehension

```
dc = dict()
for x in range(1,5):
    dc[x]=x**3
print(dc)
```

{1: 1, 2: 8, 3: 27, 4: 64}

## EXAMPLE - Dict Comprehension

```
# Dict of cubes(values) of number(key) 1 to 4
dc = {x: x ** 3 for x in range(1, 5) }
print(dc)
```

## OUTPUT

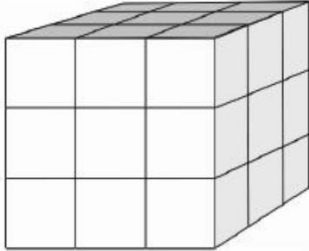

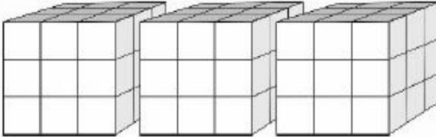

{1: 1, 2: 8, 3: 27, 4: 64}

# Very brief introduction on NumPy

Major data structures: **Ndarray**, i.e, Multidimensional array.

- A 1-D array is like a list of numbers in Python (but you will see later that the two are very different).
- A 2-D array corresponds to a matrix (table).
- A 3-D array corresponds to a cube

Illustration	Dimensions	Description
	0	Single value
	1	Multiple single values (List)
	2	Multiple List of values (Matrix)
	3	Multiple Matrices of values (Cube)
	4	Collection of Cubes
...	...	...

# Very brief introduction on NumPy

- **Element-wise computation:**

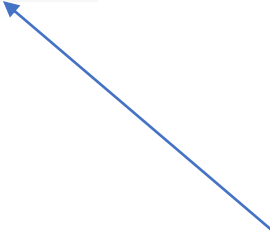

NumPy provides a set of functions for performing element-wise computation with arrays and mathematical operations between arrays. (More details about element-wise computation will be given a few slides later.)

- Some algorithms can have a considerable performance increase after using numpy.

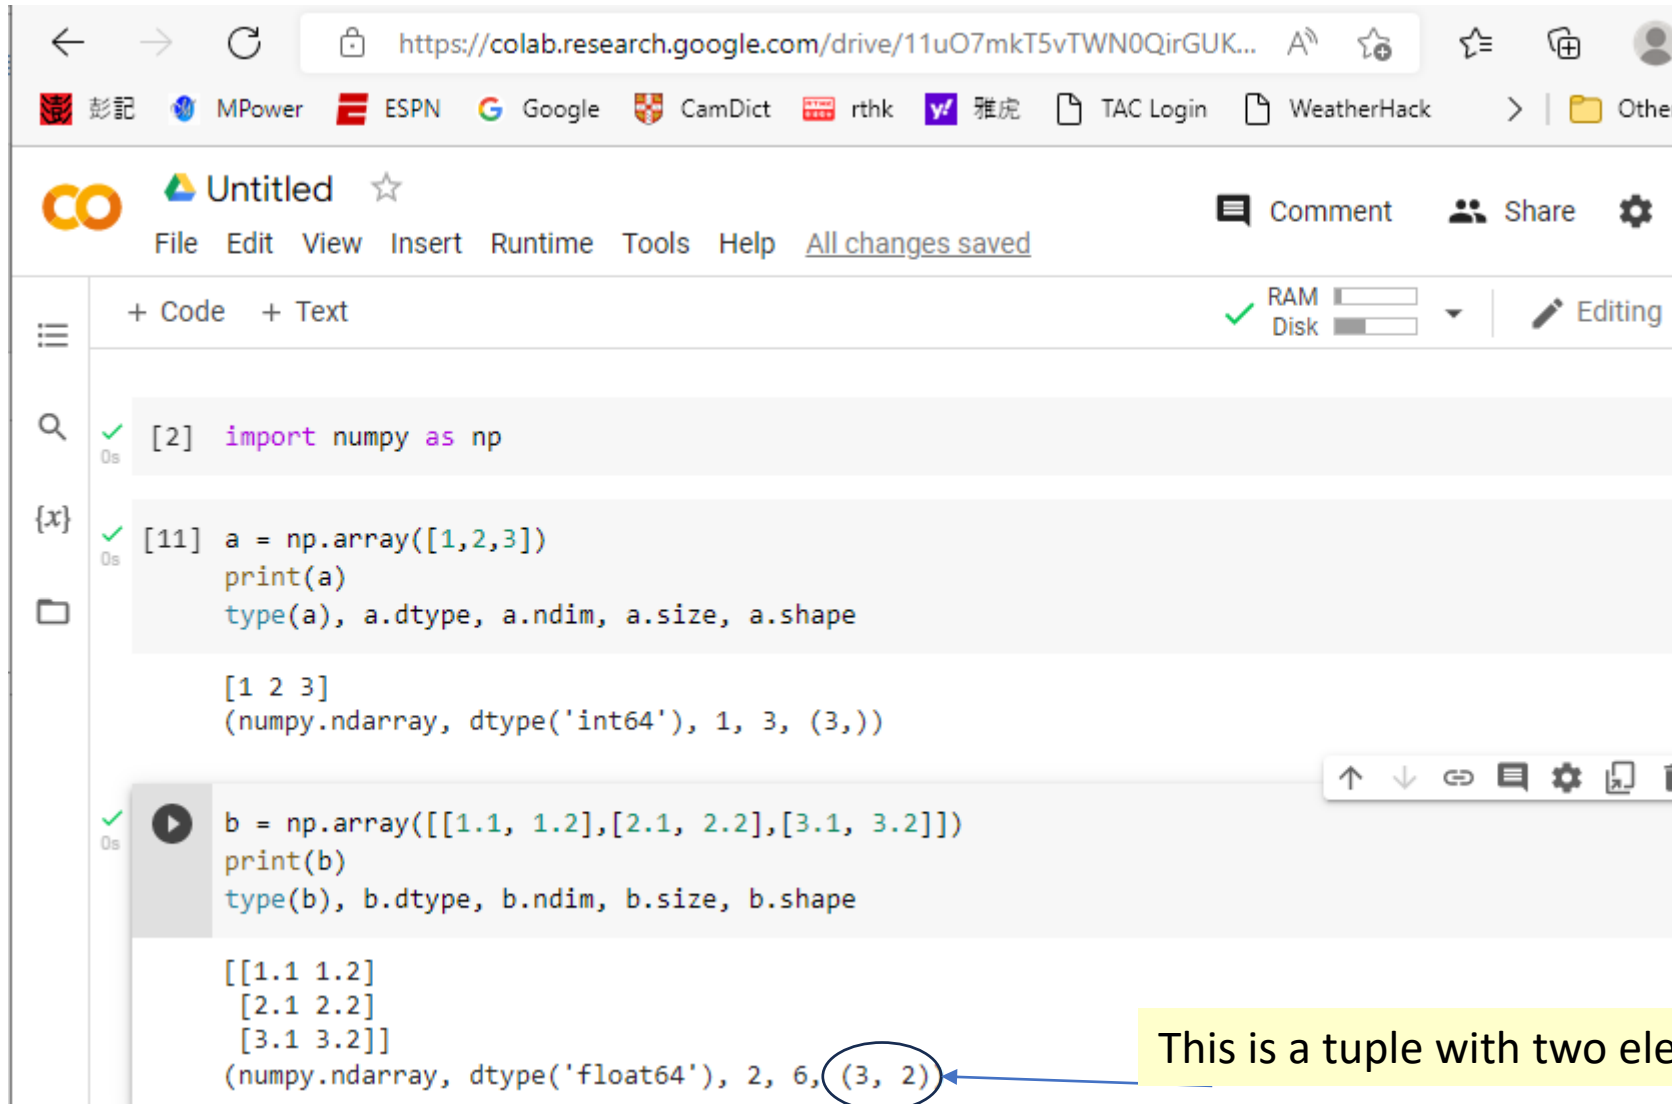

# How to import numpy into your program?

```
import numpy as np
```

Not compulsory, but is very commonly used “name” for calling numpy

# Constructing a numpy array from a Python list

The screenshot shows a Google Colab notebook interface. The browser address bar displays the URL: `https://colab.research.google.com/drive/11uO7mkT5vTWN0QirGUK...`. The notebook has a menu bar with options: File, Edit, View, Insert, Runtime, Tools, Help, and a status bar indicating 'All changes saved'. The left sidebar shows a file explorer with a folder icon. The main code area contains three code cells. The first cell imports NumPy as `np`. The second cell creates a 1D array `a` from the list `[1, 2, 3]` and prints its details. The third cell creates a 2D array `b` from a list of lists and prints its details. The output of the third cell shows the array `b` and its properties, with the shape `(3, 2)` circled in blue. A yellow callout box points to this shape with the text 'This is a tuple with two elements.'

```
[2] import numpy as np

[11] a = np.array([1,2,3])
      print(a)
      type(a), a.dtype, a.ndim, a.size, a.shape

      [1 2 3]
      (numpy.ndarray, dtype('int64'), 1, 3, (3,))

b = np.array([[1.1, 1.2],[2.1, 2.2],[3.1, 3.2]])
print(b)
type(b), b.dtype, b.ndim, b.size, b.shape

[[1.1 1.2]
 [2.1 2.2]
 [3.1 3.2]]
(numpy.ndarray, dtype('float64'), 2, 6, (3, 2))
```

This is a tuple with two elements.

# Constructing a numpy array from a Python list

```
[2] import numpy as np

[11] a = np.array([1,2,3])
      print(a)
      type(a), a.dtype, a.ndim, a.size, a.shape

[1  2  3]
(numpy.ndarray, dtype('int64'), 1, 3, (3,))

b = np.array([[1.1, 1.2],[2.1, 2.2],[3.1, 3.2]])
print(b)
type(b), b.dtype, b.ndim, b.size, b.shape

[[1.1  1.2]
 [2.1  2.2]
 [3.1  3.2]]
(numpy.ndarray, dtype('float64'), 2, 6, (3, 2))
```

This is a tuple with one element.

**Warning:** (3, ) and (3) are different:  
(3, ) is a tuple with one element  
(3) is the integer 3

Example:

Remember the repetitive operator for list: `[1, 2, 3] * 2 == [1, 2, 3, 1, 2, 3]`

```
print([3] * 2)
print((3,) * 2)
print((3) * 2)
```

```
[3, 3]
(3, 3)
6
```

# Simple ways to create filled ndarray

```
[18] np.zeros((2,3))
```

```
array([[0., 0., 0.],  
       [0., 0., 0.]])
```

```
[19] np.ones((4,2))
```

```
array([[1., 1.],  
       [1., 1.],  
       [1., 1.],  
       [1., 1.]])
```

```
[20] np.arange(0,10,2)
```

```
array([0, 2, 4, 6, 8])
```

```
[21] np.arange(0,6,0.6)
```

```
array([0. , 0.6, 1.2, 1.8, 2.4, 3. , 3.6, 4.2, 4.8, 5.4])
```

```
np.linspace(0,10,5)
```

```
array([ 0. , 2.5, 5. , 7.5, 10. ])
```

```
[24] np.random.random(3)
```

```
array([0.77826755, 0.51211508, 0.48279984])
```

```
np.random.random((4,2))
```

```
array([[0.05478554, 0.46322134],  
       [0.53737229, 0.11105537],  
       [0.82457384, 0.96234194],  
       [0.0962791 , 0.25828843]])
```

# Simple ways to create filled ndarray

```
[18] np.zeros((2,3))  
  
array([[0., 0., 0.],  
       [0., 0., 0.]])
```

```
[19] np.ones((4,2))  
  
array([[1., 1.],  
       [1., 1.],  
       [1., 1.],  
       [1., 1.]])
```

```
[20] np.arange(0,10,2)  
  
array([0, 2, 4, 6, 8])
```

```
[21] np.arange(0,6,0.6)  
  
array([0. , 0.6, 1.2, 1.8, 2.4, 3. , 3.6, 4.2, 4.8, 5.4])
```

```
np.linspace(0,10,5)  
  
array([ 0. , 2.5, 5. , 7.5, 10. ])
```

```
import matplotlib.pyplot as plt  
  
x = np.linspace(0, 10, 5)  
y = x  
plt.plot(x, y)
```

[<matplotlib.lines.Line2D at 0x2ced4a9a310>]

very useful for plotting graph

# Reshaping an array

b

```
array([[ 0,  1,  2],  
       [ 3,  4,  5],  
       [ 6,  7,  8],  
       [ 9, 10, 11]])
```

```
c = b.reshape(2,6)
```

c

```
array([[ 0,  1,  2,  3,  4,  5],  
       [ 6,  7,  8,  9, 10, 11]])
```

---

Create a empty 2D array c with  
shape (2, 6)

and pick the entries from b from left to right, top to bottom,  
and put them in c one by one from left to right, top to bottom

# Reshaping an array

b

```
array([[ 0,  1,  2],  
       [ 3,  4,  5],  
       [ 6,  7,  8],  
       [ 9, 10, 11]])
```

```
c = b.reshape(2,6)
```

c

```
array([[ 0,  1,  2,  3,  4,  5],  
       [ 6,  7,  8,  9, 10, 11]])
```

Create a empty 2D array c with  
shape (2, 6)

and pick the entries from b from left to right, top to bottom,  
and put them in c one by one from left to right, top to bottom

Note: Recall that shape is a tuple, so  
the call `reshape(2, 6)` should be  
`reshape((2, 6))`. But in Python, we can  
eliminate the parathesis enclosing the  
tuple, i.e., (2, 6) is the same as 2, 6.

# Reshaping an array

```
a = np.array([1,2,3,4,5,6])  
a, a.shape
```

```
(array([1, 2, 3, 4, 5, 6]), (6,))
```

---

```
a.reshape(3,2)
```

```
array([[1, 2],  
       [3, 4],  
       [5, 6]])
```

```
a.reshape(3,-1)
```

```
array([[1, 2],  
       [3, 4],  
       [5, 6]])
```

# Reshaping an array

```
a = np.array([1,2,3,4,5,6])  
a, a.shape  
  
(array([1, 2, 3, 4, 5, 6]), (6,))
```

- If we set a dimension to -1, the actual value of this dimension is computed (inferred) from the size and the remaining dimensions.
- reshape() will not modify the array, instead, it returns another array with the new shape.

---

```
a.reshape(3,2)  
  
array([[1, 2],  
       [3, 4],  
       [5, 6]])
```

```
a.reshape(3,-1)  
  
array([[1, 2],  
       [3, 4],  
       [5, 6]])
```

# Element-wise operations

An ndarray is **very different** from the standard Python list:

```
[26] a = [1,2,3]  
      b = [10, 20, 30]  
      a+b
```

```
[1, 2, 3, 10, 20, 30]
```

```
a = np.array([1,2,3])  
b = np.array([10,20,30])  
a+b
```

```
array([11, 22, 33])
```

# Element-wise operations

Some simple examples:

[illegible]

# Element-wise on functions

Consider the following example:

```
b = np.arange(12).reshape(2,6)
print(b)
print(b+2)
print(np.sqrt(b))
```

```
[[ 0  1  2  3  4  5]
 [ 6  7  8  9 10 11]]
[[ 2  3  4  5  6  7]
 [ 8  9 10 11 12 13]]
[[0.          1.          1.41421356  1.73205081  2.          2.23606798]
 [2.44948974  2.64575131  2.82842712  3.          3.16227766  3.31662479]]
```

# Element-wise on functions

Consider the following example:

```
b = np.arange(12).reshape(2,6)
print(b)
print(b+2)
print(np.sqrt(b))
```

```
[[ 0  1  2  3  4  5]
 [ 6  7  8  9 10 11]]
[[ 2  3  4  5  6  7]
 [ 8  9 10 11 12 13]]
```

```
[[0.         1.         1.41421356 1.73205081 2.         2.23606798]
 [2.44948974 2.64575131 2.82842712 3.0        3.16227766 3.31662479]]
```

??? the two operands not with the same shape???

Because of the “**Broadcasting**” capability of numpy.

Broadcasting is a great feature that allows great flexibility.

Shortly, broadcasting is the ability to perform an operation between arrays that do not have the exact same size or shape!

# Broadcasting

```
a = np.array([1., 0., -1., 2.])  
b = a + 1  
c = a + np.ones(4)  
print(b)  
print(c)
```

## OUTPUTS

```
[2.  1.  0.  3.]  
[2.  1.  0.  3.]
```

```
a = np.array([[1., 0.],  
              [-1., 2.]])  
b = np.array([3., 1.])  
c = a + b  
print(c)
```

## OUTPUTS

```
[[4.  1.]  
 [2.  3.]]
```

# Broadcasting

```
a = np.array([1., 0., -1., 2.])
b = a + 1
c = a + np.ones(4)
print(b)
print(c)
```

**OUTPUTS**

```
[2.  1.  0.  3.]
[2.  1.  0.  3.]
```

The general rules for numpy array broadcasting are rather complicated. Later, we will only broadcast a value, or an 1D array to some multi-dimensional array

```
a = np.array([[1., 0.],
              [-1., 2.]])
b = a + np.array([3., 1.])
```

**OUTPUTS**

```
[[4.  1.]
 [2.  3.]]
```

# Conditions, Boolean Arrays and Selection

```
[46] A = np.random.random((4,4))
```

```
A
```

```
array([[0.35660508, 0.96118156, 0.54066201, 0.60913444],  
       [0.77205799, 0.92219434, 0.85651754, 0.76912115],  
       [0.19362348, 0.09213051, 0.90208505, 0.669729  ],  
       [0.78381514, 0.32448186, 0.94835817, 0.21323069]])
```

```
[48] cond = A < 0.5
```

```
cond
```

```
array([[ True, False, False, False],  
       [False, False, False, False],  
       [ True,  True, False, False],  
       [False,  True, False,  True]])
```

```
[49] A[cond]
```

```
array([0.35660508, 0.19362348, 0.09213051, 0.32448186, 0.21323069])
```

```
[50] A[ A < 0.5 ]
```

```
array([0.35660508, 0.19362348, 0.09213051, 0.32448186, 0.21323069])
```

# Indexing and slicing an ndarray

Just like a Python list, we can access an ndarray by indexing or by slicing.

```
A = np.arange(0, 18).reshape(3,6)  
A
```

```
array([[ 0,  1,  2,  3,  4,  5],  
       [ 6,  7,  8,  9, 10, 11],  
       [12, 13, 14, 15, 16, 17]])
```

```
A[0,0], A[1,1], A[2,2]
```

```
(0, 7, 14)
```

```
A[1, 1:4]
```

```
array([7, 8, 9])
```

# Indexing and slicing an ndarray

Just like a Python list, we can access an ndarray by indexing or by slicing.

row with index 0, 1, 2  
column with index  
0, 1, 2, 3, 4, 5

```
A = np.arange(0, 18).reshape(3,6)
A
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11],
       [12, 13, 14, 15, 16, 17]])
```

```
A[0,0], A[1,1], A[2,2]
(0, 7, 14)
```

the stopping index  
is not included in  
the “output”.

```
A[1, 1:4]
array([7, 8, 9])
```

```
A[1]
array([ 6,  7,  8,  9, 10, 11])
```

# Indexing and slicing an ndarray

Another example:

```
[37] A = np.arange(0,18).reshape(3,6)
      A
      array([[ 0,  1,  2,  3,  4,  5],
             [ 6,  7,  8,  9, 10, 11],
             [12, 13, 14, 15, 16, 17]])
```

```
▶ A[0:2,0:4]
   array([[0, 1, 2, 3],
          [6, 7, 8, 9]])
```

# Indexing and slicing an ndarray

- Positive and Negative indices
  - We can access any specific element in an ndarray by its positive index  $p$  and its negative index  $n$

$a[3] = a[-6] = 4.4$

	1.1	2.2	3.3	4.4	5.5	6.6	7.7	8.8	9.9
$a =$	0	1	2	3	4	5	6	7	8
	-9	-8	-7	-6	-5	-4	-3	-2	-1

- Relationship between  $n$  and  $p$ :  $p = n + \text{len}(a)$

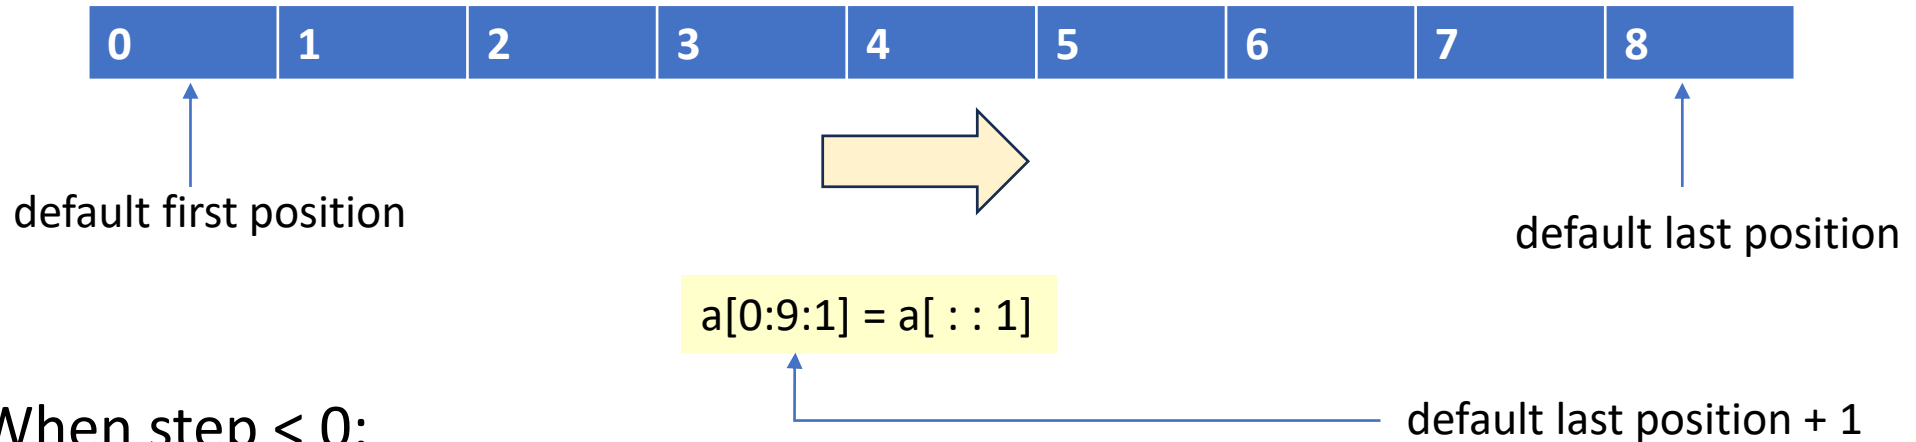

# Indexing and slicing an ndarray

	1.1	2.2	3.3	4.4	5.5	6.6	7.7	8.8	9.9
a =	0	1	2	3	4	5	6	7	8
	-9	-8	-7	-6	-5	-4	-3	-2	-1

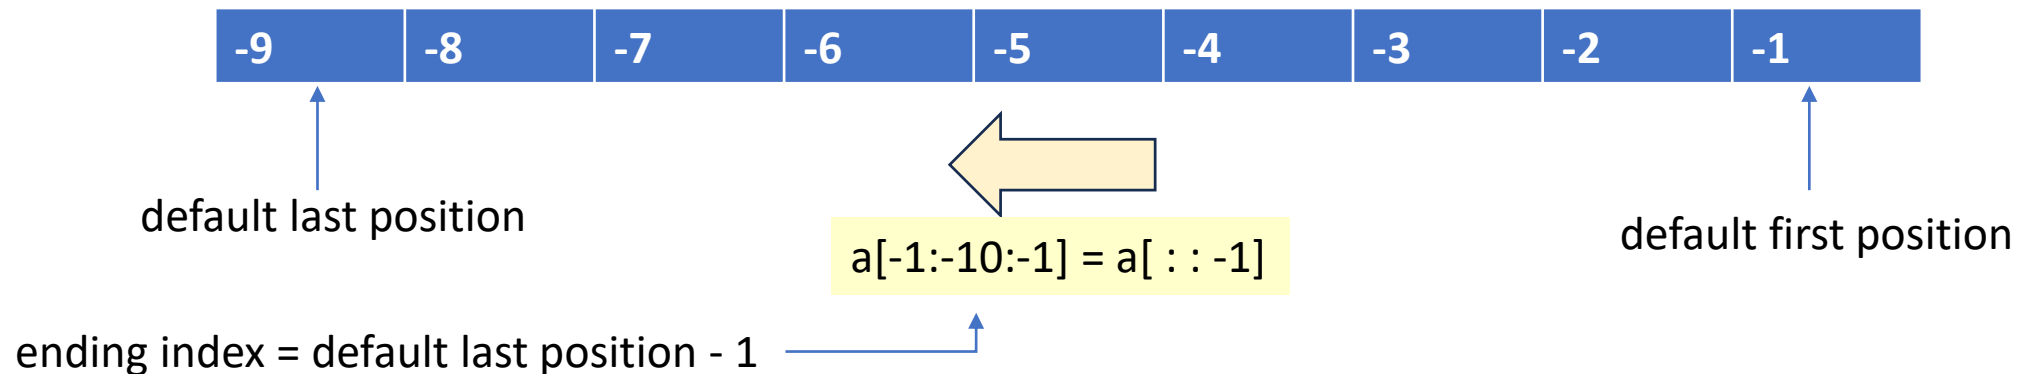

- A slice can be (i) `a[start:stop:step]` or (ii) `a[start:stop]`.  
((ii) is (i) with step having the default value 1.)
- As in Python list, the resulting slice is  
 $[start, start+step, \dots, start + k * step]$   
where  $k$  is the largest  $k$  such that  $(start + k * step) < stop$   
(Note: the slice does not include the stopping index).

# Indexing and slicing an ndarray

- Default values for the start and stop index.
  - When step > 0:

- When step < 0:

# Indexing and slicing an ndarray

a =

1.1	2.2	3.3	4.4	5.5	6.6	7.7	8.8	9.9
0	1	2	3	4	5	6	7	8
-9	-8	-7	-6	-5	-4	-3	-2	-1

Basic steps for determining a slice:

- determine the value of step
- If step > 0
  - fill in, if missing, the default start and stop index.
  - convert all negative index to the equivalent positive index
- If step < 0
  - fill in, if missing, the default start and stop index.
  - convert all positive index to the equivalent negative index
- Determine the slice

Exercises:

`a[::-1]`

`a[1::-1]`

`a[-3:-1]`

`a[-2:]`

`a[:-2]`

# The Ellipsis

```
x = np.array([[[1,10,100],[2,20,200],[3,30,300]],  
              [[4,40,400],[5,50,500],[6,60,600]]])  
x.shape, x
```

```
((2, 3, 3),  
 array([[[ 1, 10, 100],  
         [ 2, 20, 200],  
         [ 3, 30, 300]],  
        [[ 4, 40, 400],  
         [ 5, 50, 500],  
         [ 6, 60, 600]]]))
```

```
y = x[:, :, 0:2]  
y.shape, y
```

```
((2, 3, 2),  
 array([[[ 1, 10],  
         [ 2, 20],  
         [ 3, 30]],  
        [[ 4, 40],  
         [ 5, 50],  
         [ 6, 60]]]))
```

# The Ellipsis

```
x = np.array([[[1,10,100],[2,20,200],[3,30,300]],  
             [[4,40,400],[5,50,500],[6,60,600]]])  
x.shape, x
```

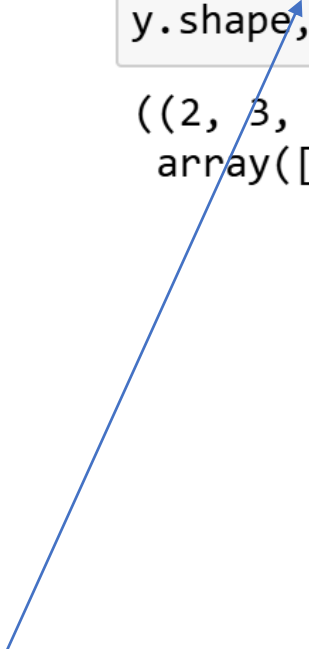

```
((2, 3, 3),  
 array([[[ 1, 10, 100],  
         [ 2, 20, 200],  
         [ 3, 30, 300]],  
        [[ 4, 40, 400],  
         [ 5, 50, 500],  
         [ 6, 60, 600]]]))
```

```
y = x[:, :, 0:2]  
y.shape, y
```

```
((2, 3, 2),  
 array([[[ 1, 10],  
         [ 2, 20],  
         [ 3, 30]],  
        [[ 4, 40],  
         [ 5, 50],  
         [ 6, 60]]]))
```

```
y = x[... , 0:2]  
y.shape, y
```

```
((2, 3, 2),  
 array([[[ 1, 10],  
         [ 2, 20],  
         [ 3, 30]],  
        [[ 4, 40],  
         [ 5, 50],  
         [ 6, 60]]]))
```

The ellipsis automatically expands the necessary number of ':'.  

# Very brief introduction of Pandas

- Pandas: A powerful Python Data Analysis Library
- The library was designed and developed primarily by Wes McKinney starting in 2008. In 2012, Sien Chang, one of his colleagues, was added to the development. Together they set up one of the most used libraries in the Python community.
- Pandas supports two major data structures:
  - Series: Extension of Numpy's 1D-array
  - Dataframes: A 2D table
- ```
import pandas as pd
```

# Series

- Series is the Pandas 1-dimensional structure. It is a useful extension of Numpy array.
- Extension of the notion of index: **index** and **index label**
- index: position of the values: 0, 1, 2, ...
- index label: give a **name** to the each index in a Series.
- If index labels are not provided in its creation, they follows the usual index sequence, i.e., 0, 1, 2, ...

# Creating Series: using the `pd.Series` method

Create a Series from a Python list

```
s = pd.Series([12, -4, 7, 9], index=['a', 'b', 'c', 'd'])  
s
```

```
a    12  
b    -4  
c     7  
d     9  
dtype: int64
```

```
s = pd.Series([12, -4, 7, 9])  
s
```

```
0    12  
1    -4  
2     7  
3     9  
dtype: int64
```

index label

# Creating Series: using the `pd.Series` method

- Create a series from a Python dictionary

```
tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}  
type(tdict), tdict
```

```
(dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
t = pd.Series(tdict)  
t
```

```
Tom      12  
Peter    -4  
Mary      7  
Zoe       9  
dtype: int64
```

# Creating Series: using the `pd.Series` method

- Create a series from a Python dictionary

```
tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}  
type(tdict), tdict
```

```
(dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
t = pd.Series(tdict)  
t
```

```
Tom      12  
Peter    -4  
Mary      7  
Zoe       9  
dtype: int64
```

caution: dict does not have order  
→ you cannot be sure the order of  
the series constructed

Obtain the values only (i.e., without row labels)

```
[11] tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}
      type(tdict), tdict
      (dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
[12] t = pd.Series(tdict)
      t
```

```
Tom      12
Peter    -4
Mary       7
Zoe        9
dtype: int64
```

```
t.values|
```

```
array([12, -4,  7,  9])
```

# Access the elements in a Series

```
[11] tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}
      type(tdict), tdict
      (dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
[12] t = pd.Series(tdict)
      t
```

```
Tom      12
Peter    -4
Mary      7
Zoe       9
dtype: int64
```

```
t.values|
```

```
array([12, -4,  7,  9])
```

We have two ways to access the elements of a Series:

- (1) using the **index** as if it is a numpy array; or
- (2) using the series's **index labels**

```
[14] t[3], t['Zoe']
```

```
(9, 9)
```

```
[17] t[0:3]
```

```
Tom      12
Peter    -4
Mary      7
dtype: int64
```

```
t['Tom':'Mary']
```

```
Tom      12
Peter    -4
Mary      7
dtype: int64
```

```
[20] t[[0,2]]
```

```
Tom      12
Mary      7
dtype: int64
```

```
[21] t[['Tom','Mary']]
```

```
Tom      12
Mary      7
dtype: int64
```

# Access the elements in a Series

```
[11] tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}
      type(tdict), tdict
      (dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
[12] t = pd.Series(tdict)
      t
```

```
Tom      12
Peter    -4
Mary      7
Zoe       9
dtype: int64
```

Be very careful

The stopping **index** is not included in the output

The stopping **index label** is included in the output

```
array([12, -4,  7,  9])
```

We have two ways to access the elements of a Series:

(1) using the **index** as if it is a numpy array; or

(2) using the series's **index labels**

```
[14] t[3], t['Zoe']
```

```
(9, 9)
```

```
[17] t[0:3]
```

```
Tom      12
Peter    -4
Mary      7
dtype: int64
```

```
[20] t[[0,2]]
```

```
Tom      12
Mary      7
dtype: int64
```

```
[21] t[['Tom','Mary']]
```

```
Tom      12
Mary      7
dtype: int64
```

```
t['Tom':'Mary']
```

```
Tom      12
Peter    -4
Mary      7
dtype: int64
```

# Like Numpy Array, element-wise operations are supported

```
[11] tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}
      type(tdict), tdict

(dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
[12] t = pd.Series(tdict)
      t
```

```
Tom      12
Peter    -4
Mary      7
Zoe       9
dtype: int64
```

```
t.values|
```

```
array([12, -4,  7,  9])
```

```
[3] t + 2
```

```
Tom      14
Peter     -2
Mary      9
Zoe      11
dtype: int64
```

```
[4] t / 3
```

```
Tom      4.000000
Peter    -1.333333
Mary      2.333333
Zoe      3.000000
dtype: float64
```

```
[5] np.square(t)
```

```
Tom      144
Peter     16
Mary      49
Zoe      81
dtype: int64
```

# Conditions and Boolean indexing are also supported

```
[11] tdict = {'Tom':12, 'Peter':-4, 'Mary':7, 'Zoe':9}
      type(tdict), tdict
      (dict, {'Mary': 7, 'Peter': -4, 'Tom': 12, 'Zoe': 9})
```

```
[12] t = pd.Series(tdict)
      t
```

```
Tom      12
Peter    -4
Mary      7
Zoe       9
dtype: int64
```

```
t.values|
```

```
array([12, -4,  7,  9])
```

```
[11] t <= 7
```

```
Tom      False
Peter     True
Mary     True
Zoe      False
dtype: bool
```

```
[12] t[t<=7]
```

```
Peter    -4
Mary      7
dtype: int64
```

# Some useful functions on Series

```
[14] s = pd.Series([1,0,2,1,2,3])
```

```
s
```

```
0    1
```

```
1    0
```

```
2    2
```

```
3    1
```

```
4    2
```

```
5    3
```

```
dtype: int64
```

```
[17] s.unique(), s.sum(), s.mean(), s.max(), s.min()
```

```
(array([1, 0, 2, 3]), 9, 1.5, 3, 0)
```

```
[18] s.value_counts()
```

```
1    2
```

```
2    2
```

```
0    1
```

```
3    1
```

```
dtype: int64
```

# DataFrame

- A DataFrame can be thought of as a table like data structure that each column is expressed as a Series.
- It can also be seen as an excel spreadsheet which offers very flexible ways of working with it.

Out[13]:

|   | year | team | ... | wins | draws | losses |
|---|------|------|-----|------|-------|--------|
| 0 | 2018 | HKU  |     | 30   | 6     | 2      |
| 1 | 2019 | HKU  |     | 28   | 7     | 3      |
| 2 | 2020 | HKU  |     | 32   | 4     | 2      |
| 3 | 2018 | CU   |     | 29   | 5     | 4      |
| 4 | 2019 | CU   |     | 32   | 4     | 2      |
| 5 | 2020 | CU   |     | 26   | 7     | 5      |
| 6 | 2018 | UST  |     | 21   | 8     | 9      |
| 7 | 2019 | UST  |     | 17   | 10    | 11     |
| 8 | 2020 | UST  |     | 19   | 8     | 11     |

Column names

Row labels

# Create a DataFrame using `pd.DataFrame`

```
[4] data = {'color': ['blue', 'green', 'yellow', 'red', 'white'],  
          'object': ['ball', 'pen', 'pencil', 'paper', 'mug'],  
          'price': [1.2, 1.0, 0.6, 0.9, 1.7]}  
frame = pd.DataFrame(data)  
frame
```

|   | color  | object | price |
|---|--------|--------|-------|
| 0 | blue   | ball   | 1.2   |
| 1 | green  | pen    | 1.0   |
| 2 | yellow | pencil | 0.6   |
| 3 | red    | paper  | 0.9   |
| 4 | white  | mug    | 1.7   |

# Create a DataFrame using `pd.DataFrame`

```
[4] data = {'color': ['blue', 'green', 'yellow', 'red', 'white'],  
          'object': ['ball', 'pen', 'pencil', 'paper', 'mug'],  
          'price': [1.2, 1.0, 0.6, 0.9, 1.7]}  
frame = pd.DataFrame(data)  
frame
```

|   | color  | object | price |
|---|--------|--------|-------|
| 0 | blue   | ball   | 1.2   |
| 1 | green  | pen    | 1.0   |
| 2 | yellow | pencil | 0.6   |
| 3 | red    | paper  | 0.9   |
| 4 | white  | mug    | 1.7   |

Sometimes, the dictionary contains many columns that are not useful, and we can select explicitly useful columns to create the DataFrame

```
frame = pd.DataFrame(data, columns=['object', 'price'])  
frame
```

|   | object | price |
|---|--------|-------|
| 0 | ball   | 1.2   |
| 1 | pen    | 1.0   |
| 2 | pencil | 0.6   |
| 3 | paper  | 0.9   |
| 4 | mug    | 1.7   |

# Create a DataFrame using `pd.DataFrame`

And of course we can give labels to the indexes.

```
data = {'color': ['blue', 'green', 'yellow', 'red', 'white'],  
        'object': ['ball', 'pen', 'pencil', 'paper', 'mug'],  
        'price': [1.2, 1.0, 0.6, 0.9, 1.7]}  
frame2 = pd.DataFrame(data, index=['one', 'two', 'three', 'four', 'five'])  
frame2
```

|       | color  | object | price |
|-------|--------|--------|-------|
| one   | blue   | ball   | 1.2   |
| two   | green  | pen    | 1.0   |
| three | yellow | pencil | 0.6   |
| four  | red    | paper  | 0.9   |
| five  | white  | mug    | 1.7   |

# Create a DataFrame using `pd.DataFrame`

Assigning index labels and selecting columns at the same time:

```
[10] data = {'color': ['blue', 'green', 'yellow', 'red', 'white'],  
          'object': ['ball', 'pen', 'pencil', 'paper', 'mug'],  
          'price': [1.2, 1.0, 0.6, 0.9, 1.7]}  
frame2 = pd.DataFrame(data, index=['one', 'two', 'three', 'four', 'five'],  
                      columns=['object', 'price'])  
  
frame2
```

|       | object | price |
|-------|--------|-------|
| one   | ball   | 1.2   |
| two   | pen    | 1.0   |
| three | pencil | 0.6   |
| four  | paper  | 0.9   |
| five  | mug    | 1.7   |

# Create a DataFrame using `pd.DataFrame`

In addition to dictionary, there are many other ways to create a dataframe, e.g., list of lists, 2D numpy arrays, ...

```
[13] frame3 = pd.DataFrame(np.arange(16).reshape((4,4)),  
                          index=['red','blue','yellow','white'],  
                          columns=['ball','pen','pencil','paper'])
```

frame3

|        | ball | pen | pencil | paper |
|--------|------|-----|--------|-------|
| red    | 0    | 1   | 2      | 3     |
| blue   | 4    | 5   | 6      | 7     |
| yellow | 8    | 9   | 10     | 11    |
| white  | 12   | 13  | 14     | 15    |

# Create a DataFrame using `pd.DataFrame`

## Creating a dataframe from a list of lists

```
: 1 import pandas as pd
   2
   3 t = pd.DataFrame([[1,2,3],[4,5,6]])
   4 t
```

```
:
   0 1 2
0 1 2 3
1 4 5 6
```

```
1 import pandas as pd
2
3 t = pd.DataFrame([[1,2,3],[4,5,6]],columns=['A','B','C'])
4 t
```

```
   A B C

# Selecting rows and columns

Again, be careful when slicing a DataFrame

```
f = pd.DataFrame([[1,2,3],[4,5,6],[7,8,9]], columns=['A','B','C'], index=[0,1,2])  
f
```

|   | A | B | C |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 1 | 4 | 5 | 6 |
| 2 | 7 | 8 | 9 |

`f.iloc[0:2]`

stopping  
index not  
included

|   | A | B | C |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 1 | 4 | 5 | 6 |

`f.loc[0:2]`

stopping  
index label  
included

|   | A | B | C |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 1 | 4 | 5 | 6 |
| 2 | 7 | 8 | 9 |

# Reading and writing files

---

- Most of public data are delivered in plain text format, excel format, CSV (comma-separated- value) format, or any other delimiter-separated value format.
- Pandas provides many methods for reading these files, e.g., `read_csv()`, `read_excel()`, `read_table()`, `read_clipboard()`;
- and methods for writing these files, e.g., `to_csv()`, `to_excel`, `to_table()`, ...

# An example

```
In [7]: 1 import pandas as pd
        2
        3 t = pd.read_excel("educ_uoe_fine06.xls")
        4 t
```
